

# ALMA Observing Tool Quickstart Guide

[www.almascience.org](http://www.almascience.org)

---

ALMA, an international astronomy facility, is a partnership of ESO (representing its member states), NSF (USA) and NINS (Japan), together with NRC (Canada), MOST and ASIAA (Taiwan), and KASI (Republic of Korea), in cooperation with the Republic of Chile. The Joint ALMA Observatory is operated by ESO, AUI/NRAO and NAOJ.

## User Support:

For further information or to comment on this document, please contact your regional Helpdesk through the ALMA User Portal at [www.almascience.org](http://www.almascience.org). Helpdesk tickets will be directed to the appropriate ALMA Regional Centre at ESO, NAOJ or NRAO.

# 1 Scope

This document is intended as a concise guide to Phase-1 proposal preparation in Cycle 8 2021 for novice and experienced ALMA users alike. While novice users should carefully follow the step-by-step instructions, experienced users may want to concentrate on the boxed texts. These highlight new features, useful tips and tricks, and issues to be aware of, and can be identified by the corresponding icons.

A more comprehensive description of the OT and the different aspects of proposal preparation can be found in the [ALMA OT User Manual](#). The [ALMA OT Reference Manual](#) provides a more concise explanation for all the fields and menu items in the OT, and can be accessed interactively from within the OT by clicking on the ‘?’ icons. **The User Manual and Reference Manual can also be accessed and interactively searched via the Help menu in the OT.** The OT also contains helpful tooltips that appear when you mouse-over text boxes or radio buttons.

Unfortunately, the screenshots have not been updated since Cycle 5, but the OT’s appearance has not greatly changed since then.

# 2 Getting Started

In order to access the ALMA Archive and submit an observing proposal, you must have previously **registered** with the [ALMA Science Portal](#). You can then **download** the OT from the [OT page](#) in the ALMA Science Portal. Please follow the detailed installation instructions there; in case of any problems you can consult the [Troubleshooting page](#). Depending on your installation option, you **start the OT** either by double-clicking on an ALMA OT icon (installer) or from the command line by executing a script (e.g. `./ALMA-OT.sh` on Linux) in the installation directory (tarball). An initial dialogue box with different options will appear. To follow the step-by-step guide for creating a new proposal please select the first option, *Create a new proposal*.

The option to install the OT using Web Start is no longer available as the application now runs on Java 11. At the same time, all versions of the OT will come with a version of Java and thus it is no longer necessary for a user to install the right version of Java on their machine. To replace Web Start, a **new installer** has been created which will lead the user through the steps required to install the OT and allow the memory to be changed from its default of 4 GB. More memory might be necessary for complicated proposals requiring many Science Goals or containing many sources. The tarball installation method remains available. Detailed instructions can be found in the Science Portal.

It is possible to re-use a proposal from a previous cycle as a template for your new proposal using the *File > Open Project as New Proposal* feature. Regardless of its status (e.g. it might have been accepted and had SBs generated) it will be retrieved from the ALMA archive and open in the OT as a new Phase 1 proposal without a project code. Any Phase-2 materials (e.g. SBs) will have been removed. Note that time estimates, allowed configurations etc. may have changed from previous cycles. This feature also allows conversion between normal and DDT proposals.

Alternatively, once the OT has opened you can select the green *New Proposal (Phase 1)* button from the toolbar in the OT. You will be presented with the window shown in Fig. 1, which illustrates the main Graphical User Interface (GUI) components:

**Menu:** Allows access to all functions available in the OT via pop-up submenus.

**Toolbar:** A selection of icons for some of the most frequently used functions in the Menu.

**Project Structure Pane:** Visualisation and navigation of the **Project Tree**. Each part of the tree is known as a “node” and many of these can be expanded or collapsed by clicking (“turning”) the handle icons.

Figure 1: OT Graphical User Interface.

A convenient shortcut for expansion of all nodes below a given node is to click there and then type Ctrl- or Cmd-Z.

**Editor Pane:** The technical specifications of the project are filled and edited in this pane. The content of the editor pane changes depending on the branch of the Project Tree selected. For spatial and spectral setup, the editor pane is composed of several panels.

**Feedback Pane:** Provides feedback on the validation process and allows you to identify problems with your proposal.

**Overview Pane:** Informative summary of the proposal creation process and contextual help.

You can customize the GUI according to your needs. The size of the different panes can be modified by clicking and dragging their borders, or maximised/minimised by clicking on the triangular arrow symbols. You can toggle the *Overview* and *Feedback* panes by clicking on *View > Feedback/Overview* in the Menu, e.g. in order to maximise the Editor pane. The *Feedback* pane will normally not be visible upon starting the OT, but it will pop up when the project is validated (see Section 11). You can customise the OT further by selecting *File > Preferences*. In particular, you may want to change the font size or colour scheme, or preferentially show certain editors.

### 3 General Proposal Information

Start by **filling the fields in the Proposal editor** labelled *Proposal Title* and *Abstract*, select the *Proposal Type* and *Scientific Category* using the radio buttons and choose up to two *Keywords* from a list (to select multiple keywords hold the Ctrl button or the Cmd button on Macs).

#### Special Proposal Types

**Target of Opportunity (ToO)** proposals are designed for observations that can be anticipated, but for which the source coordinates and the timing are not known at proposal submission time. Examples of typical ToO targets are supernovae, gamma ray bursts or transients. A proposal that simply has time constraints is not a ToO but should instead be submitted as a Regular proposal, with the requested time constraints specified in the *Control And Performance* editor (see Section 9).

**VLBI** proposals use ALMA in conjunction with VLBI telescopes around the world. They have a special VLBI proposal interface at the Science Goal level and the spectral setup is limited to pre-defined continuum setups in Bands 3 and 6. Users should normally select the system-defined calibration option as all necessary calibrations will be carried out by the observatory. Unlike standard proposals, VLBI observations require a time estimate (including overheads, which make up ~50 per cent of the expected time on source) rather than a sensitivity to be entered. Note that ALMA VLBI programs must also have been submitted to the appropriate VLBI network by their independent deadline. Passive phasing can be used to enable the detection of weaker (<0.5 Jy) science targets.

**Phased Array** proposals request that the 12-m Array be used as a single dish i.e. using the same phasing hardware that produces the signal used for VLBI, but without correlating this with the signals from other telescopes – it is an ALMA-only mode. This mode is currently only available for the observation of pulsars.

**Large Programs** are proposals that require more than 50 hours of 12-m Array time, or more than 150 hours of 7-m array time requested as part of stand-alone Atacama Compact Array (ACA, also known as the Morita Array) Science Goals. For these programs, co-PIs may be specified and the observing time required will be split between the PI and co-PIs' Executives (Europe, North America, East Asia or Chile).

The definition of Stand-alone ACA (SACA) Large Programs has changed and the limit of 150 hours now only applies to the 7-m Array time associated with SACA Science Goals. The estimated TP Array time is now irrelevant for the purposes of defining whether a proposal is a Large Program or not.

It is now possible to observe pulsars with ALMA. This is done by selecting the Phased Array proposal type. Observations may only be made of known pulsars and passive phasing is enforced as pulsars are weak emitters at mm wavelengths. A fixed-frequency setup in Band 3 is the only spectral setup currently allowed in this mode.

In order for you to be able to submit the proposal, you will have to **select yourself as PI** by scrolling down, pressing the *Select PI* button and searching by name, email or ALMA ID in the pop-up window (see Fig. 2). The ALMA ID is your Science Portal login.

You can select an unlimited number of Co-Is in a similar way, **provided that they have previously registered with the ALMA Science Portal**. Please make sure they do so at least 24 hours prior to the submission deadline. If you have a long list of Co-Is you may prefer to add them from a proposal previously saved on disk using the *Add from proposal* button.

Figure 2: Selecting the PI and Co-Is in the Proposal editor using the User Registry search interface.

As ALMA is now using dual-anonymous proposal review, the Cover Sheet will no longer show the names of any of the investigators. Guidelines on how to write the scientific justification in such a way that it does not betray the identity of the author can be found in the [Proposer's Guide](#).

Proposal review for small proposals, those requesting <25 hours, will now be done using distributed peer review i.e. the reviewing will be done by the PIs submitting such proposals. Unless Large Program is selected, the OT will require that one of the investigators be selected as a proposal reviewer. If this person is the PI and does not have a PhD, a mentor can be named who would assist the PI with the reviewing.

You are not required to indicate if your proposal constitutes a **re-submission**. This will be determined by the observatory (please refer to the [Proposer's Guide](#) for details). However, you should justify any duplicate observations of archival data or previously accepted programs.

The *Science Case* used for the the scientific assessment of your proposal needs to be **attached as a PDF file not exceeding 4 pages in total (6 pages for Large Programs)**, including any figures and tables. The science case should put the proposed observations in a broad scientific context, highlight their impact on the field of research and present the immediate goal you expect to achieve. With the move to dual anonymous proposal review, all PDFs should be written in a neutral style such that it is not possible for the reader to determine the identity of the author. More information can be found in the [Proposer's Guide](#).

While the text of the technical justification is entered directly into the OT (see Section 10), any associated figures must still be included in the PDF. For more details please refer to the [Proposer's Guide](#).

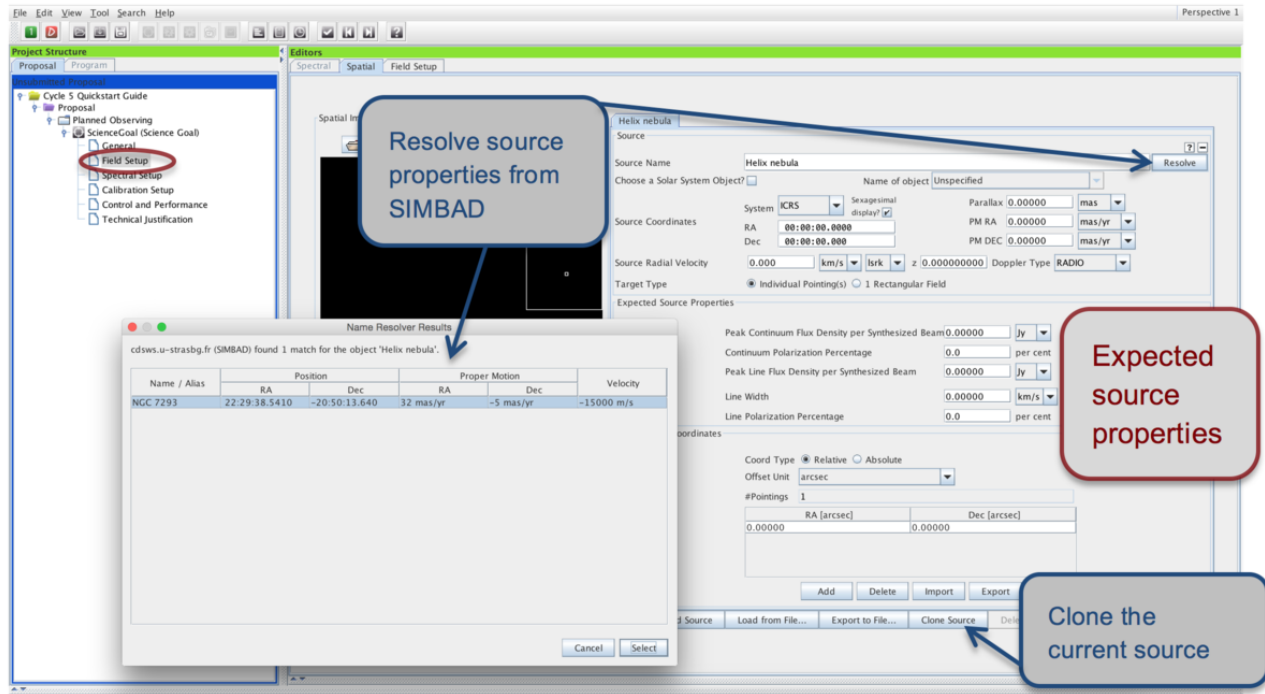

Figure 3: Adding the source information in the Field Setup editor.

Large Programs must now include a Management Plan as a separate PDF. Only a single page is allowed.

The fonts used in the PDFs must have a minimum size of 12 points. The OT will now issue an **error** if >15 per cent of the text is smaller than 12 points – this was only a warning in Cycle 7. Be aware that an image cropped from another PDF may contain text that lay outside of the cropped area, even though this is not displayed.

## 4 Science Goals

All the technical specifications for your project are contained in one or more Science Goals, each of which contains six nodes covering different aspects of the observations. Each Science Goal may contain one or more sources of the same Target Type (individual pointing(s) or 1 rectangular mosaic) and is limited to one correlator setup with up to five frequency tunings, one calibration strategy and one set of Control and Performance parameters (see Section 9). You **create a new Science Goal** by clicking on the *New Phase 1 Science Goal* icon in the toolbar or selecting *Edit > New Phase 1 Science Goal* from the menu bar.

Right-clicking on the *Science Goal* node in the Project Tree will allow you to select a number of actions to be performed, such as **renaming, copying or deleting the Science Goal**. Some of the actions (e.g. copying) are also available for nodes **within** a Science Goal, e.g. the Spectral Setup. It is important to understand that Science Goals can only be pasted at the *Proposal* or *Planned Observing* node level, and parts of a Science Goal can only be pasted at the *Science Goal* node level (i.e. a higher-level node must be selected and right-clicked

after copying in order to bring up the *paste* action). You cannot paste a Science Goal into another Science Goal. Copy and paste of a Science Goal or parts of a Science Goal can also be achieved with the usual Ctrl-C and Ctrl-V keyboard shortcuts or by dragging and dropping.

## 5 Source Information

A source can contain either one or more (overlapping) individual pointings or 1 rectangular mosaic. All pointings defined in a given source share the velocity information and Expected Source Properties. Setting up the actual pointings within a source is covered in Section 7. For the moment, it is sufficient to enter the source information, especially the velocity, as this will be used for the spectral setup.

By default, the *Field Setup* editor contains one source tab. The first thing to select is the Target Type: *Individual Pointing(s)* or *1 Rectangular field*. The Target Type must be the same for all sources in a Science Goal, and it is not possible to switch to *1 Rectangular field* once additional sources have been added. You can then use the *Add source* button at the very bottom to open additional source tabs. **You will need to specify the source information for each source individually.** If your source has an entry in SIMBAD or NED, you can simply type its name in the *Source Name* field and hit *Resolve* to import the field centre coordinate and velocity information from there (see Fig. 3). Otherwise, this information must be entered by hand. Solar System targets, including the Sun, can be selected from a pull-down list if the *Choose a Solar System Object* box is checked.

Within a Science Goal, the OT uses a clustering algorithm to group sources within  $10^\circ$  into separate SBs ( $1^\circ$  for long-baseline SGs) to allow good phase calibration of all sources. Information on the different source clusters can be found in the *Time Estimate* pop-up available from the *Control and Performance* node. A source cluster can contain a maximum of 150 pointings.

Galactic coordinates are supported. The spatial visualiser will display externally loaded images in Galactic coordinates correctly and will also convert between different coordinate systems. For example, if the source information is defined in Galactic coordinates and the displayed image uses ICRS/J2000 (as is always the case for the OT's default image servers) the rectangle will be rotated to show the correct orientation in the ICRS frame. Source coordinates read in via a text file will be interpreted as Galactic if they are given in decimal degrees.

For each source, you are required to provide an estimate of the expected source properties. The peak flux density entered should be an estimate of the **weakest component** driving the sensitivity requirement of your Science Goal. For continuum observations only the *Peak Continuum Flux Density per Beam* is required, while for spectral line and spectral scan observations the *Peak Line Flux Density per Beam* and the (FWHM) *Line Width* must be specified. In the latter case it may also be appropriate to enter the *Peak Continuum Flux Density per Beam* if you want to observe both lines and continuum. The *Line/Continuum Polarization Percentages* are required only if full-polarization observations are requested. The expected source parameters entered are used to calculate a number of quantities in the Technical Justification editor (see Section 10) and the proposal/Science Goal Summary Sheets. They should be used for guidance when choosing the correlator setup and sensitivity requirements for your Science Goal.

**It is your responsibility to ensure that the source information is correct.** The source coordinates and the velocity are used by the OT to calculate the pointing(s) and the sky frequencies respectively, and can normally not be changed after a proposal has been accepted. The expected source properties are used for the technical feasibility assessment of your proposal, and incorrect or incomplete information may lead to the rejection of your proposal on technical grounds. For more information on how to convert existing flux measurements for your source to the peak flux density per synthesised beam required by the OT please see [this](#) and [this](#) Knowledgebase article, or consult video number 2 available [here](#).

If you have a large number of sources, you may prefer to read in the complete source information from an ASCII file using the *Load from File...* button at the bottom of the Field Setup editor. As with adding sources manually you should make sure that the correct Target Type is set **before** you load the source list. For the required file format, please see the *Field Setup* section of the [ALMA OT Reference Manual](#).

For solar observing you should specify the solar activity level and potentially enter a dummy ephemeris file created using the [ALMA Solar Ephemeris Generator](#). The ephemeris will be updated in coordination with the observatory before any observations take place. Solar observing is currently restricted to continuum setups only. Unlike most ALMA proposals, you do not request a sensitivity and instead enter the **on-source time** required on the interferometric array – observations with the Total Power Array will be added automatically and provide a map of the entire solar disc.

The only source property required for VLBI observing is whether the source is so faint ( $<0.5$  Jy) that passive phasing will be required. In this mode, the phasing up of the antennas in the 12-m Array is performed on a nearby calibrator and these then retained when observing the science target. This mode is enforced if the Phased Array is requested. If selected, it will be necessary to define a **fixed phase calibrator** in the *Calibration Setup*.

## 6 The Spectral Setup

In the *Spectral Setup* editor, start by selecting the *Spectral Type* and the *Polarization Products Desired* as these will influence the choices you have for defining your spectral setup. In particular, selecting *Full* polarization will limit you to measurements in Bands 3, 4, 5, 6 and 7. If you are not interested in polarization information you should generally leave the radio button set to the default of *Dual*. *XX* polarization is appropriate only if you need extremely fine spectral resolution ( $<30$  kHz).

High-frequency observations (Bands 9 and 10) are now available on the stand-alone ACA. It is, however, still not possible to observe in these bands on the TP Array.

**90-degree Walsh switching** is available in Bands 9 and 10. This allows the user to access the information not only from the spectral windows specified, but also from the resulting “image” spectral windows which lie in the other sideband and which were being suppressed in previous cycles. Note that **only the actual spectral windows can actively be defined in the spectral line table**, and that the image spectral windows will automatically shift anytime LO1 is recomputed (e.g. if additional spectral windows are added, or the bandwidth is changed). Walsh switching is activated by ticking the *Produce image sidebands* option in the *Spectral Type* section. If you select this option you will be given the option to view the frequencies of the image spectral windows with the *Show image spectral windows* tick-box (see Fig. 6). Walsh switching **is available only when all spectral windows in the setup use the widest (1875 MHz bandwidth) correlator mode**. Note that storing (and delivery to the PI) of the image spectral window data can be switched on or off for each spectral window individually using the *Store Image* tickbox. For the *Single Continuum* (see Fig. 8) and *Spectral Scan* spectral types with 1875-MHz-wide spectral windows, Walsh switching is automatically enabled by the OT – the user has no choice in the matter.

### 6.1 Spectral Line

Selecting *Spectral Line* will present you with a spectral window table for each of four available basebands. Unless your Science Goal requires more than 4 spectral windows, **you will normally define one spectral window per baseband**. It is good practice to fill any basebands not needed for spectral line observations with continuum spectral windows as this aids calibration, especially in the case of narrow spectral windows.

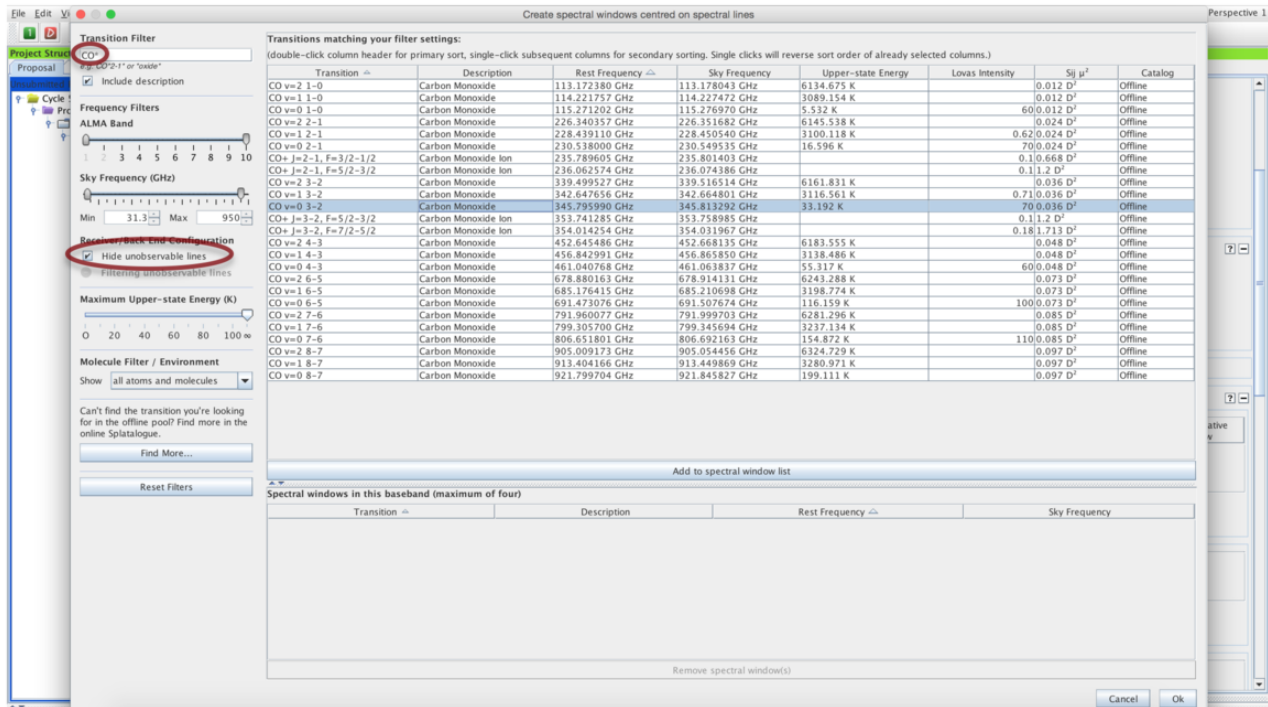

Figure 4: The Spectral Line Selector tool.

For Bands 3 to 8, for technical reasons it is not possible to place three basebands in one of the sidebands and one in the other. This restriction does not apply to Bands 9 and 10.

You define spectral windows individually for each baseband using either the *Add Spectral Window Centred on a Spectral Line* or the *Add Spectral Window Manually* buttons. The first option brings up the **Spectral Line Selector** tool (see Fig. 4) which allows you to search an extensive database (The Splatalogue – <https://splatalogue.online>) for popular transitions based on species, ALMA Band, sky frequency, maximum upper-state energy or molecules detected in a variety of astronomical sources. Simply select the transition you want, press *Add to spectral window list* and a spectral window centred on the transition will be created upon closing the tool. The second option *Add Spectral Window Manually* allows you to manually enter a spectral window central frequency. Conversion between rest and sky frequencies is automatically performed based on the source velocities defined in Section 5.

If you cannot find the transition you want in the Spectral Line Selector tool, try the *Search Online* button: you will then be able to search online from a more extensive database. By default, the Spectral Line Selector shows only transitions that are simultaneously observable with any other transitions already defined in the spectral setup; untick the *Hide unobservable lines* option to display all transitions corresponding to the search criteria.

Figure 5: Visualisation of spectral line observations in the Spectral Setup editor.

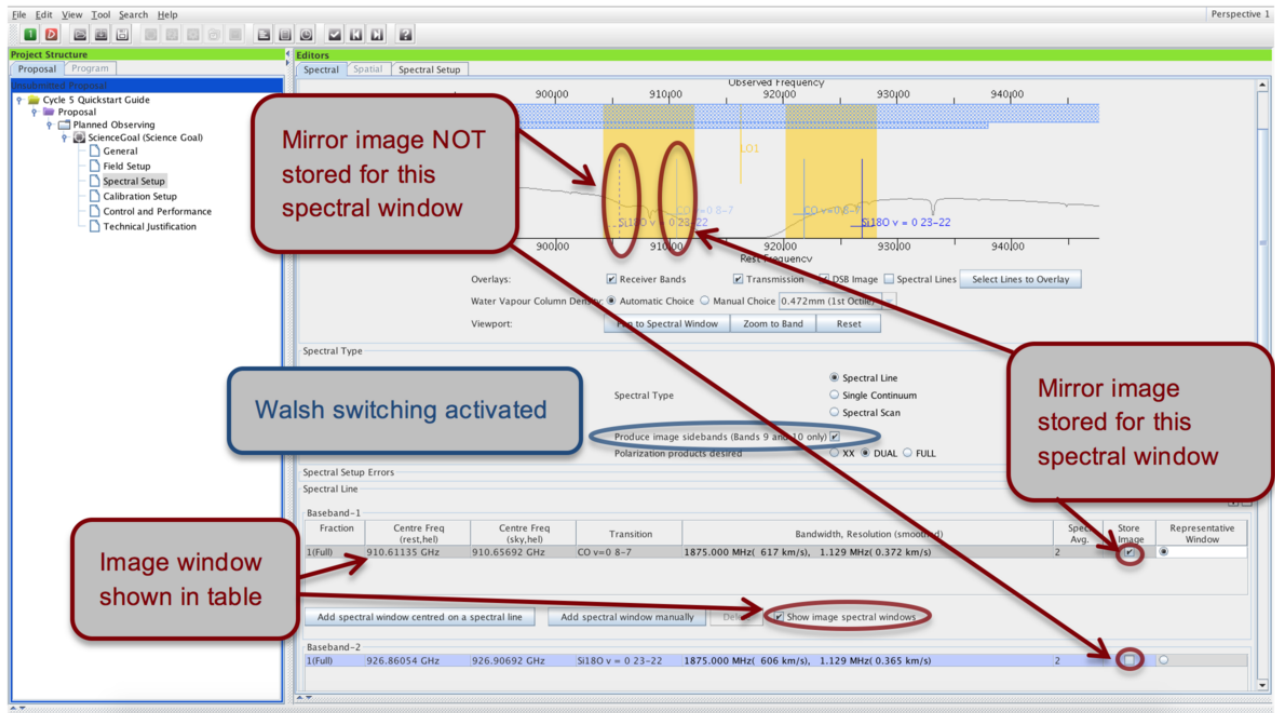

Figure 6: Spectral line observations with Walsh switching turned on, and the mirror image saved for one of the spectral windows.

Spectral windows must be associated with a correlator mode which can be selected independently for each baseband. Double-click on the entry in the *Bandwidth, Resolution* column to bring up the list of available options. The entry in bold text corresponds to the lowest spectral resolution (single-continuum) mode – **TDM**. All other modes have much higher spectral resolution and are referred to as **FDM**. Please make sure that the bandwidth and resolution selected for each spectral window are appropriate for the expected spectral properties of your source(s) as entered in Section 5.

The **spectral averaging factor** is by default set to 2 in order to lower data rates. Note that an averaging factor of 2 degrades the spectral resolution only marginally (by  $\sim 15$  per cent) but halves the data rate for that spectral window. You can modify the spectral averaging factor by double-clicking on the default ‘2’ entry in the *Spec Avg.* column of the spectral window table. This will bring up a list of possible spectral averaging factors. Selecting one of the values will immediately change the spectral resolution in the table. No spectral averaging is possible for TDM spectral windows.

The OT enforces a strict upper limit of  $70 \text{ MB s}^{-1}$  for the data rate of the 64-input correlator (used for 12-m configurations). In addition, this is calculated using 50 antennas, the maximum that might be used during an observation. Although the sensitivity calculations are all made using 43 antennas, 50 is assumed for the data rate as the SB will not run if  $70 \text{ MB s}^{-1}$  is exceeded. This figure refers to the ‘peak’ data rate i.e. the instantaneous value written out by the correlator. If the limit of  $70 \text{ MB s}^{-1}$  is exceeded, spectral averaging should be used (or spectral windows removed) until the validation error disappears.

The data rate of the ACA correlator is also checked. Exceeding the maximum data rate will though be quite difficult and is most likely to affect large TP mapping areas with four FDM spectral windows.

Based on the spectral windows defined, the OT will try to configure a spectral setup and display it in the spectral visualiser (see Fig. 5). In order for your proposal to pass validation, **all spectral windows for all source velocities must fit within a valid sideband configuration and the same ALMA Band**. If several sources with different velocities were specified in Section 5, the OT will generate up to 5 separate frequency tunings based on the velocities, the width of the spectral windows and spectral line width entered in the Expected Source Properties. The number of tunings may affect the time estimate for a Science Goal and can be checked in the *Time Estimate* dialogue (see Section 9).

It is possible to define up to 4 spectral windows per baseband, yielding a maximum total of 16 spectral windows in a single spectral setup containing 4 basebands. Simply press *Add Spectral Window Centred on a Spectral Line* or *Add Spectral Window Manually* to place extra spectral windows in the baseband tables. Because only a fixed number of channels are available for each baseband they must be divided between the spectral windows defined, implying that at a given resolution the bandwidth available for each of two spectral windows will be half that available for a single spectral window. Therefore, the fraction of the baseband assigned to each spectral window must be changed in such a way that the sum of all fractions does not exceed 1. The available choices for the correlator modes in the *Bandwidth, Resolution* field will then be automatically updated to reflect the lower number of channels available. Note that **within a baseband** all spectral windows must have the same spectral resolution (before spectral averaging).

## 6.2 Single Continuum

Selecting the *Single continuum* option is basically a shortcut to defining 4 continuum (TDM) spectral windows maximising the available bandwidth (see Fig. 8). You are presented with a drop-down list of **standard continuum frequency setups** for each of the available ALMA Bands, chosen so as to optimise atmospheric transparency. The sky frequency of the setup can be changed to anything that still yields a valid spectral setup, but any deviation from the standard frequencies must be fully justified in Section 10.

A new option has been added to the Single Continuum interface that enables the use of the FDM correlator mode. This provides much higher spectral resolution than TDM and can be useful, for example, if a continuum spectra is contaminated with narrow spectral lines.

*Single Continuum* and *Spectral Scan* observations are specified in the “sky” (observed) reference frame. Unlike *Spectral Line* mode, the velocity information entered in Section 5 is ignored in this case and all sources are observed with the same frequency tuning.

The spectral windows set up by the OT based on the input continuum frequency for each baseband are listed in the spectral window tables and displayed graphically in the spectral visualiser. Note that the sky frequency specified corresponds to the LO frequency and is not itself observed for Bands 3–8.

For Bands 9 and 10, the sky frequency corresponds to the frequency at the centre of the 8 GHz wide upper sideband. **Note that Walsh switching is always used for *Single Continuum* observations, yielding a combined bandwidth of 15 GHz in Bands 9 and 10.**

Band 5 is now available for solar observations. Available configurations are C-1, -2 and -3.

### 6.3 Spectral Scans

The *Spectral Scan* interface is a convenient way of setting up several correlator tunings to cover a wide, uninterrupted frequency range within a single ALMA Band. You need to specify the start and end frequency as well as the desired *Bandwidth*, *Resolution* of each spectral window making up the scan. A maximum of 5 tunings can be observed within one Science Goal, which means there is a trade-off between achieving a high spectral resolution and covering a wide frequency range (if you want to cover a wider frequency range than possible with 5 tunings you will have to split the spectral scan across multiple Science Goals). Spectral averaging is possible in the same way as it is for *Spectral Line* observations.

Spectral scans are now available for use with the 7-m Array, in either stand-alone mode or in conjunction with 12-m-Array observations. Spectral scans with the TP Array have not yet been commissioned.

Despite the recent increases in observing efficiency, spectral scans can still have very high time estimates. This will happen mostly for observations with relatively long on-source times and many frequency tunings. It may be more efficient to set up such spectral scans using separate Science Goals for each frequency tuning.

If the requested spectral scan can be set up successfully, the frequency tunings calculated by the OT are displayed in the spectral visualiser (see Fig. 7) and also listed in the spectral-scan table. If not, a red error message will appear, indicating the origin of the problem. Spectral-scan observations are offered only for *Individual Pointing(s)* field setups with one pointing per source and a maximum limit of 150 pointings over all tunings (i.e. for 5 tunings the maximum number of pointings is 30). **Note that for Band-9 and -10 observations Walsh switching is automatically turned on if the widest (1875 MHz) spectral windows are selected, otherwise it is turned off.**

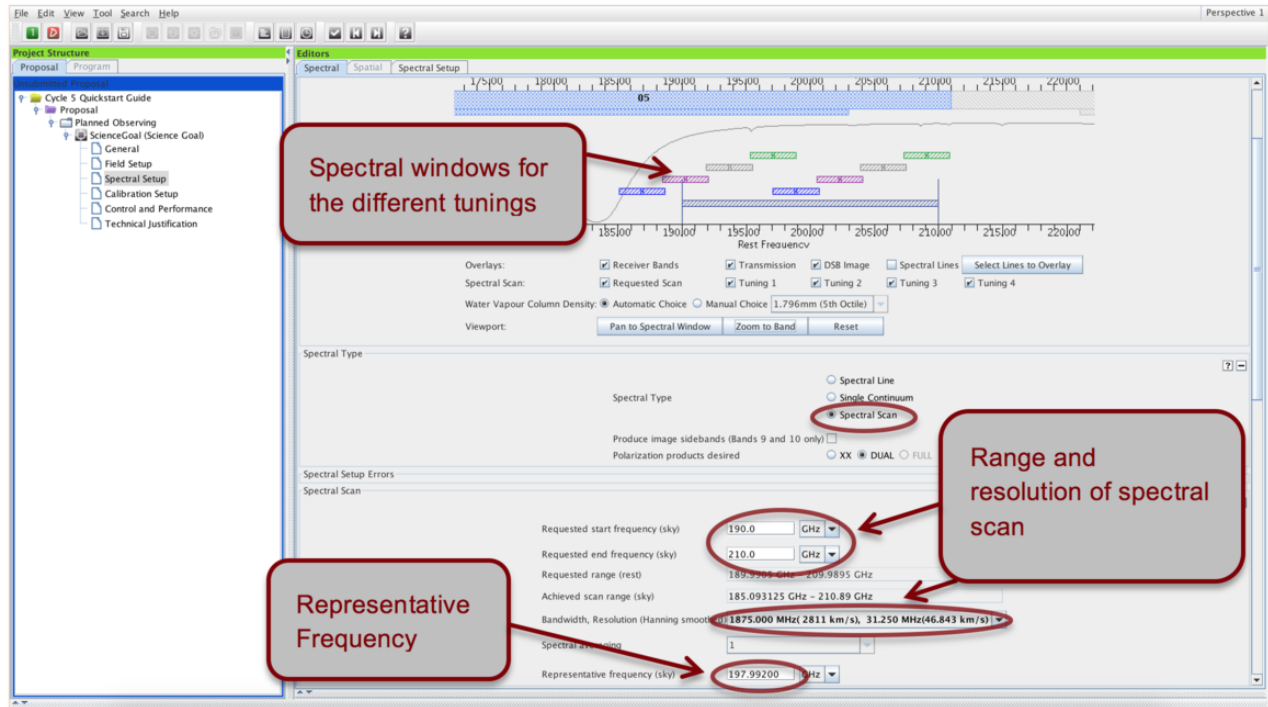

Figure 7: Visualisation of spectral-scan observations in the Spectral Setup editor.

## 6.4 The Representative Frequency

Every spectral setup is characterised by a representative frequency, which is used to compute the spatial parameters of the Science Goal (primary beam, synthesised beamsize, maximum recoverable scale) and controls the atmospheric transmission used in the time estimate (see Section 9). It defaults to the centre of one of the spectral windows defined, but can be changed by the user to lie anywhere within the spectral windows of the setup using the representative window radio button and/or typing in the relevant field below the baseband tables. For spectral line observations, the representative frequency is a rest frequency that will be transformed to a sky frequency using the velocity information for each source. **Please check it carefully for each source, and modify it if necessary.**

**The exact choice of representative frequency can severely impact the time estimate, especially in Band 5 and the higher frequency bands 7, 8, 9 and 10.** If it falls in a region of poor atmospheric transmission the time estimate will sky-rocket compared to a setup with a representative frequency in an area of good atmospheric transmission. It is important that the representative frequency is set to the line of interest that falls into the region of the poorest atmospheric transmission, otherwise the requested sensitivity will not be reached for this line.

## 6.5 Entering Rest Frequencies

You should **enter the rest frequencies of any spectral lines observed with your spectral setup** in the *Rest Frequencies* section below the spectral line tables. These will be stored and used for data reduction and quality assurance purposes (e.g. to provide the proper velocity scale for different image cubes, check that lines near the edges of spectral windows are fully observed). They do not affect the spectral setup. Clicking *Define rest frequencies* brings up an incarnation of the spectral line picker. **Any transitions used to define spectral windows in the spectral setup are automatically stored**, but we encourage users to additionally enter

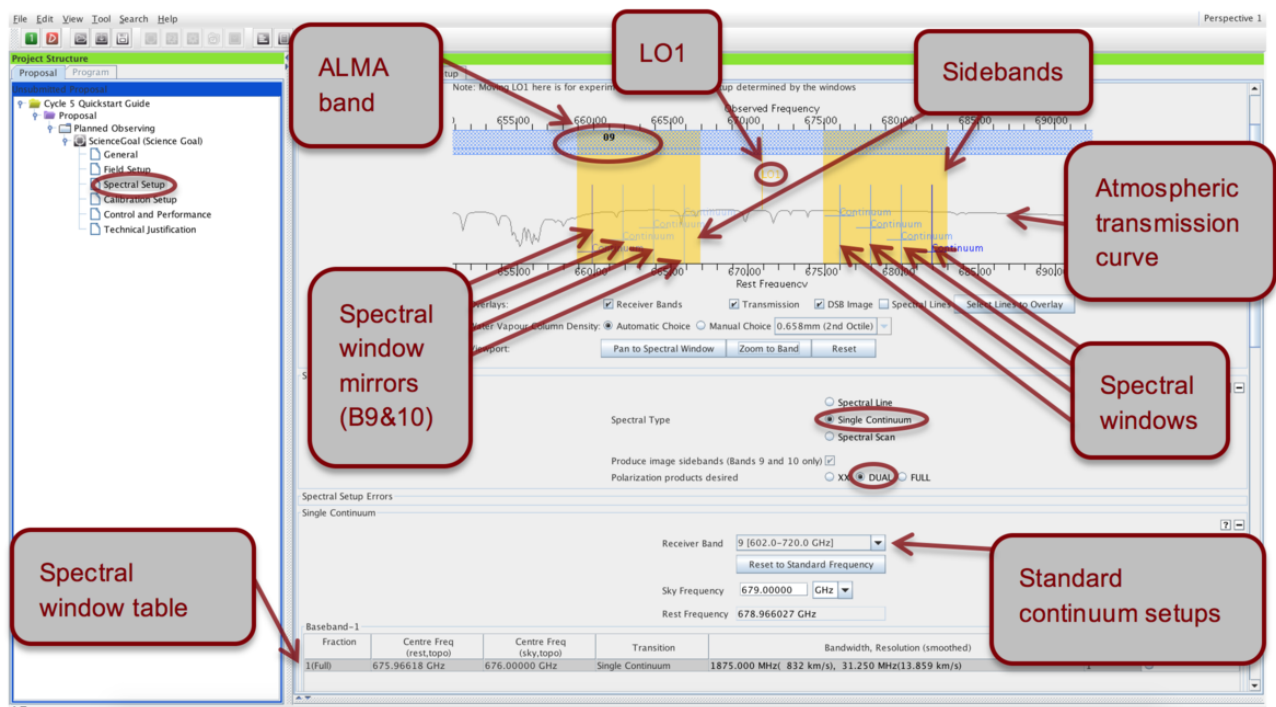

Figure 8: The Spectral Setup editor. Here, continuum observations have been defined.

any other transitions they expect to detect with the proposed observations. Only transitions falling within the spectral setup as defined are permitted.

## 6.6 The spectral visualiser

The spectral visualiser is shown by default in the *Spectral Setup* editor. It shows the ALMA Bands offered in the current cycle (Bands 3 to 10) as well as the atmospheric transmission curve of the Chajnantor site. The OT automatically chooses the water vapour column density appropriate for the observing frequency and bases the sensitivity calculation on this. **The *Manual Choice* is for visualisation purposes only and has no effect on the estimated time.** Once you specify at least one spectral window, a tuning is calculated and (yellow) sidebands appear in the visualiser. The sidebands show where basebands may be placed and do **not** indicate the frequency range that will be sampled by the observations. Up to four 2-GHz-wide basebands (not displayed in the spectral visualiser) are available within each of which one or more spectral windows may be placed. Spectral windows are defined directly by the user from within the spectral-window table and are shown in the visualiser in blue. **The LO1 frequency, sidebands and basebands are automatically calculated by the OT based on the spectral windows defined and cannot be controlled by the user directly.** If the OT cannot compute a valid spectral setup for your spectral windows, the sidebands will turn grey and an error message will appear.

You can zoom in/out of the spectral visualiser by left/right-clicking on the magnifying glass symbol cursor, or by using the *Zoom to Band* and *Reset* buttons. You can move along the frequency axis by moving the cursor near the axis and dragging the green sliding bars or using *Pan to Line*. For a practical demonstration of the spectral editor please watch the spectral setup [video tutorial](#).

## 7 Finalising the Spatial Setup

Having specified the spectral setup and in particular the representative frequency, you are now ready to finalise the spatial setup based on the sources you defined in Section 5. The maximum total number of pointings in the largest array (12-m or 7-m for Standalone ACA) is 150, regardless of whether these are treated as mosaics, offset pointings or separate sources.

Mosaics are now allowed in full-polarization mode. These can be defined in the usual way as either a collection of individual pointings or as a rectangular box that is automatically tiled by the OT. Nyquist sampling is highly recommended and for rectangular boxes the OT will warn if the pointings are sampled at less than the Nyquist frequency. If a polarization mosaic is requested, the spectral setup will be forced to a Single Continuum setup at the standard continuum frequencies for the selected band. In case high spectral resolution is required in order to remove spectral lines, the Single Continuum mode now contains the option to select FDM.

### 7.1 Individual Pointing(s)

You can visualise and configure the spatial setup for each source individually by selecting the relevant source tab. By default, there will be just one pointing at the source coordinates specified earlier. Offset pointings can be added, edited and deleted directly in the *Field Center Coordinates* panel or interactively in the Spatial Visual Editor (see boxed text). The *Import* button will read offset pointings for a given source from an ASCII file in simple RA, DEC format. You can also *Export* pointings, e.g. to be used for simulations, in different coordinate formats.

Non-overlapping offset pointings are no longer allowed within one field source. Instead, **all pointings within one field source must overlap** and will be processed as one image.

If ACA 7-m observations are requested (Section 9) these will have the same pointing centres as the 12-m pointings defined; any custom-defined mosaic will not be adjusted for the larger primary beam size of the 7-m antennas. Also, the sensitivity specified in Section 9 is assumed to be per pointing and the estimate entered should take into account any overlap.

### 7.2 1 Rectangular Field

By default, the spatial editor shows only the rectangular area defined for the mosaic. To see the individual pointings set up by the OT, you need to press the *Show pointing positions* button in the toolbar above the spatial editor.

The *Rectangular Field* option is a convenient way to easily set up evenly sampled rectangular mosaics on a per-source basis. You simply specify the size of the field as *p length* times *q length*, the *Position Angle* and the *Spacing* of individual pointings. By default, the spacing is set to Nyquist sampling ( $Spacing = 0.51 \text{ times fraction of antenna beamsize}$ ). If you change this, you must carefully justify your choice in the *Technical Justification* (Section 10). For rectangular fields, the 7-m Array pointings are automatically set up to optimally sample the area specified, therefore the number of pointings will be smaller than for the 12-m Array. You may wish to export the coordinates of the individual pointings; this is done using the *Export* button next to the displayed number of pointings.

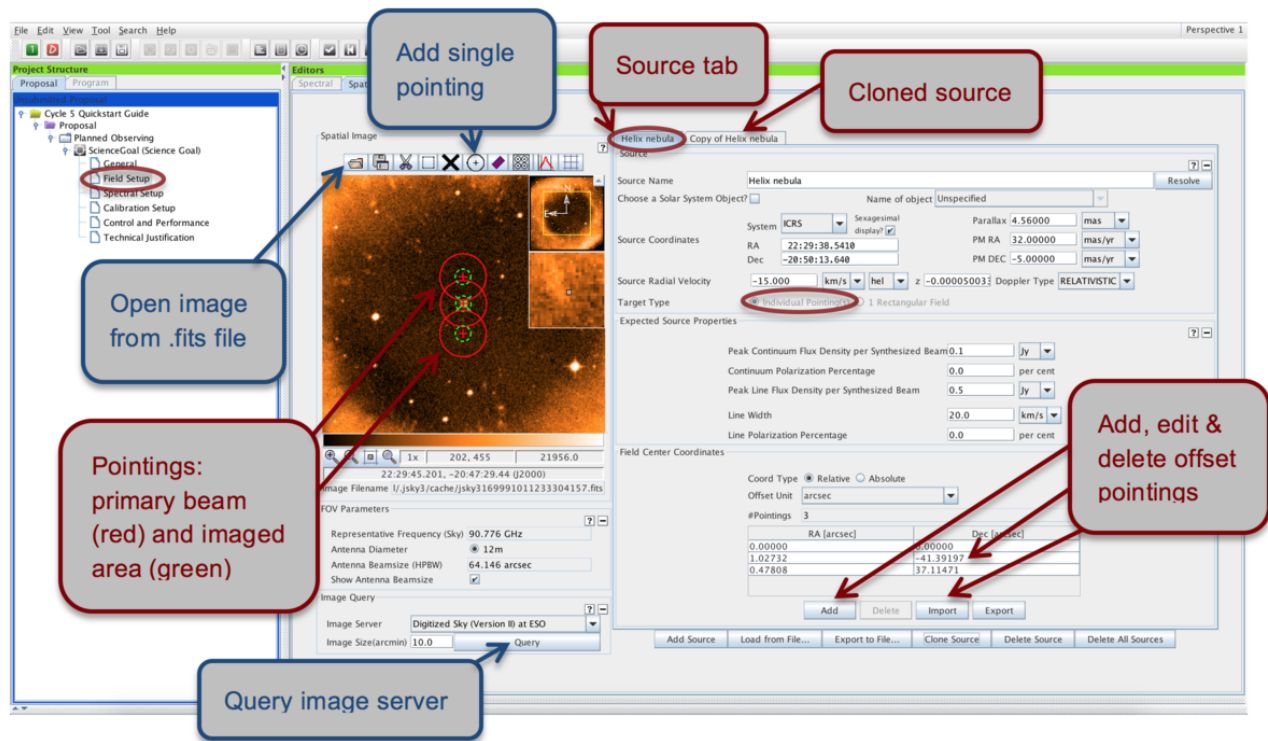

Figure 9: Visualisation of individual pointings in the spatial tab of the Field Setup editor.

### 7.3 The spatial visualiser

The spatial visualiser (see Figs 9 and 10) is found under the *Spatial* tab of the *Field Setup* editor. It can be used to view and edit pointings **on a per-source basis** and will work properly only if you load an image. Either *Query* one of the image servers selected from the drop-down menu to display a catalogue image of the area surrounding your source, or load and display your own FITS image by clicking the folder icon in the spatial editor toolbar. The primary beams of the pointings defined are represented by red circles, and can be moved, added and deleted interactively. They can be displayed for either the 12- or 7-m antennas if ACA observations have been requested. If Total Power observations are requested, the area scanned is shown by a turquoise box. For individual pointings, this box dynamically adapts to cover the pointings defined. You can use the buttons in the toolbar above and below the spatial visualiser to perform simple visualisation operations such as adjusting the cut levels, zooming, and saving the image. Please see the spatial setup [video tutorial](#) for a practical demonstration of all functionalities.

The sensitivity in a single pointing is not uniform, but gradually falls off away from the pointing centre. For rectangular mosaics, the fall-off in sensitivity is automatically taken into account by the fact that the individual pointings are set up so as to overlap. The HPBW of the antenna beam is represented by a red circle in the spatial visualiser and a smaller green circle (1/3 of the HPBW) is shown to emphasize the inner area where the sensitivity is highest.

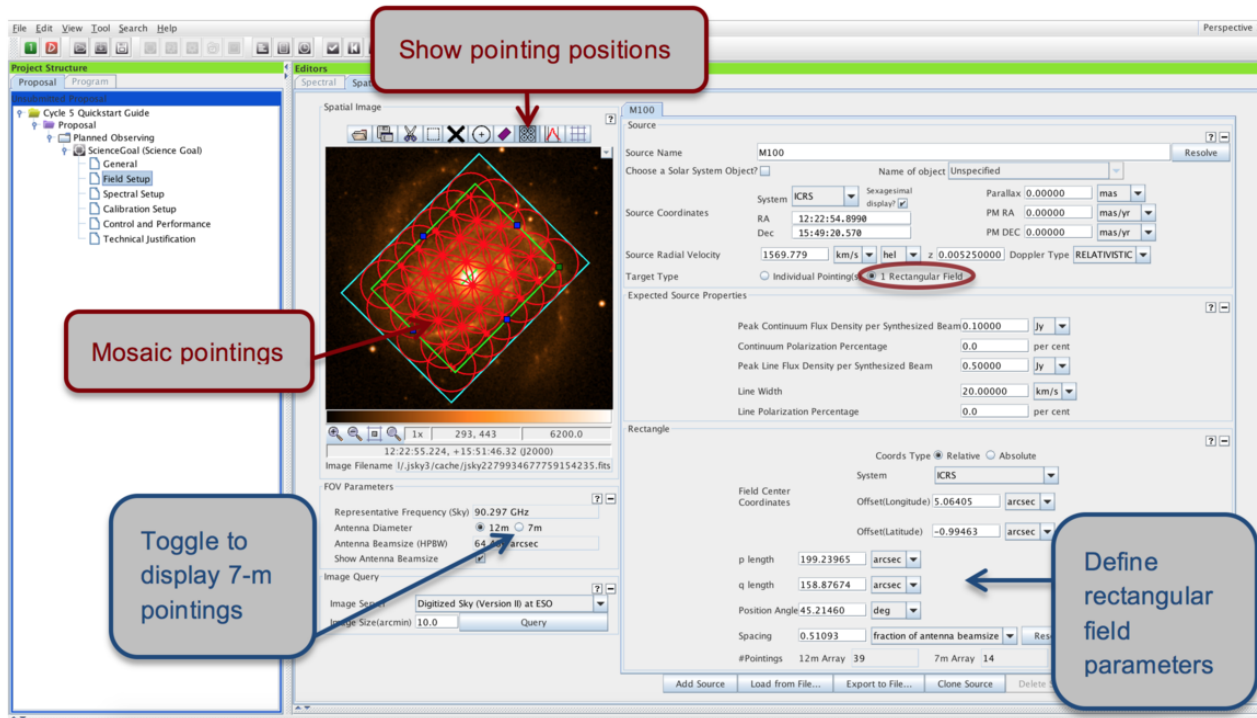

Figure 10: Visualisation of a rectangular mosaic.

## 8 Calibration Strategy

You should normally use the default *System-defined calibration* option in the *Calibration Setup* editor. The system-defined calibration is designed to fully calibrate your science observations using the most appropriate sources available at execution time, and will at least include pointing, bandpass/flux and phase calibration. Science Goals requiring full polarization will receive an appropriate calibration strategy. Only experts whose projects have special calibration requirements should specify *User-defined calibration*.

An extra option is available for the system-defined calibration strategy: *force separate amplitude calibration using solar system object*. By default, the OT assumes that it is acceptable to use the same quasar for both amplitude and bandpass calibration. However, if you have any special amplitude calibration requirements **you can force an extra observation of a Solar System object to be taken for amplitude calibration**. This will add a few minutes to your time estimate (see Section 9).

If passive phasing has been selected, you will need to define a fixed (specific) phase calibrator instead of a query. The user-defined calibration interface should have been selected automatically and the existing phase query should be deleted. Then choose *Add Fixed Calibrator* and select a specific source from the ALMA calibrator catalogue. Calibrators need to have a flux in the band of interest  $\geq 0.5$  Jy and ideally be within  $5^\circ$  of the science target. The choice of calibrator should be described in the Technical Justification.

It is now possible to indicate whether you need better positional accuracy than is achieved using default ALMA calibration and typical observing conditions for the Representative Frequency. For more details, consult the [Proposer's Guide](#).

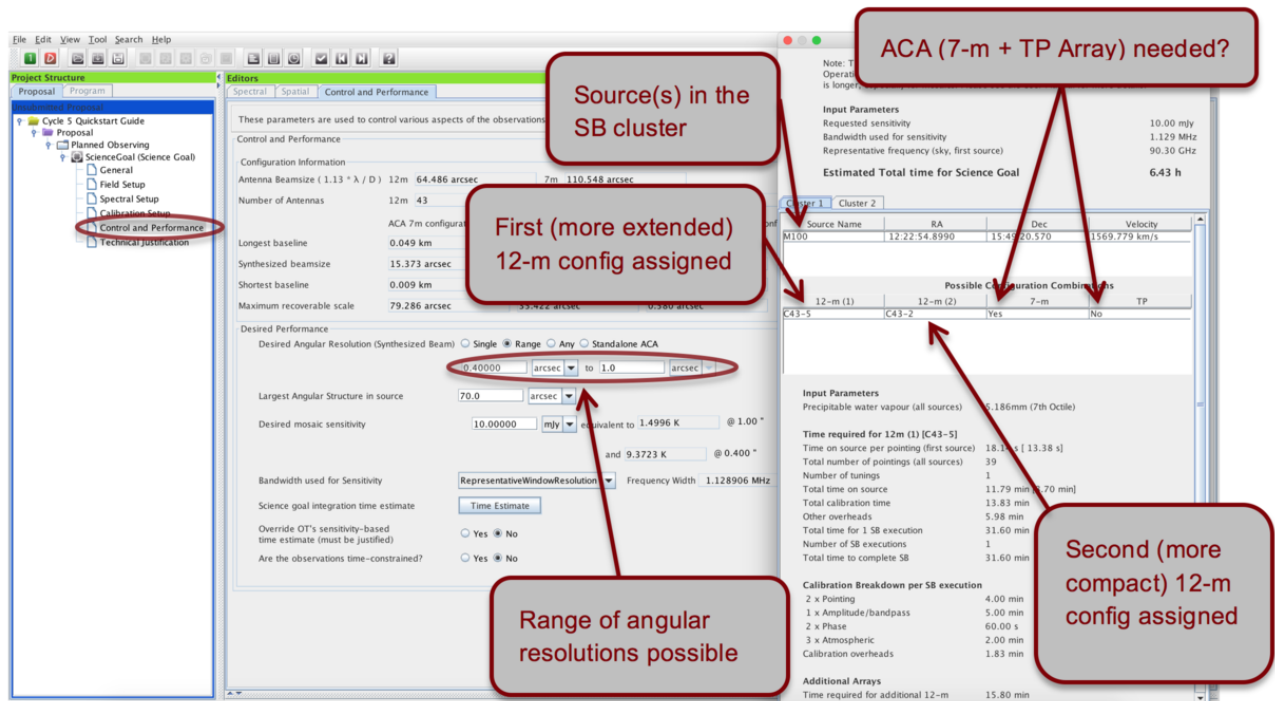

Figure 11: Control and Performance editor and the Time Estimate box. Here, a range of acceptable angular resolutions has been specified.

## 9 Control and Performance

The final technical specifications of your Science Goal are entered in the *Control and Performance* editor (see Fig. 11). The *Configuration Information* section at the top of the page displays information on the array configurations available in the current cycle, and uses the representative frequency defined in the spectral setup to calculate the *Synthesized beamsize* and the *Maximum Recoverable Scale* of the observations.

The Desired Angular Resolution (AR) and the Largest Angular Structure (LAS) are used together to determine the array configuration(s) the observations can be executed in. **PIs cannot explicitly request specific configurations**, but should instead make sure that the AR and LAS parameters entered are correct. The array configurations selected for your observations will together have baselines long enough to match the AR requested, and be compact enough to resolve the LAS. Often this will mean that a number of configurations are acceptable for a given Science Goal or that up to two 12-m configurations as well as ACA 7-m and TP observations are included (for limitations and possible array combinations see Section A.4 of the [Proposer's Guide](#)). Details on the configuration setup devised by the OT can be found in the *Time Estimate* pop-up.

Users do not directly select whether ACA 7-m and/or Total Power observations should be added to their 12-m observations or not. Instead, the ACA is imposed by the OT if required to achieve the LAS requested. Whether or not ACA observations will be scheduled can be easily seen in the *Time Estimate* pop-up (see Fig. 11) or the Proposal Time Summary dialogue (“clock” icon on the menu bar).

Users of the 12-m array have the option of entering a single value (as in previous cycles), a range of acceptable AR values, or asking for observations with any AR. If a range of AR values is entered, the OT will assign one

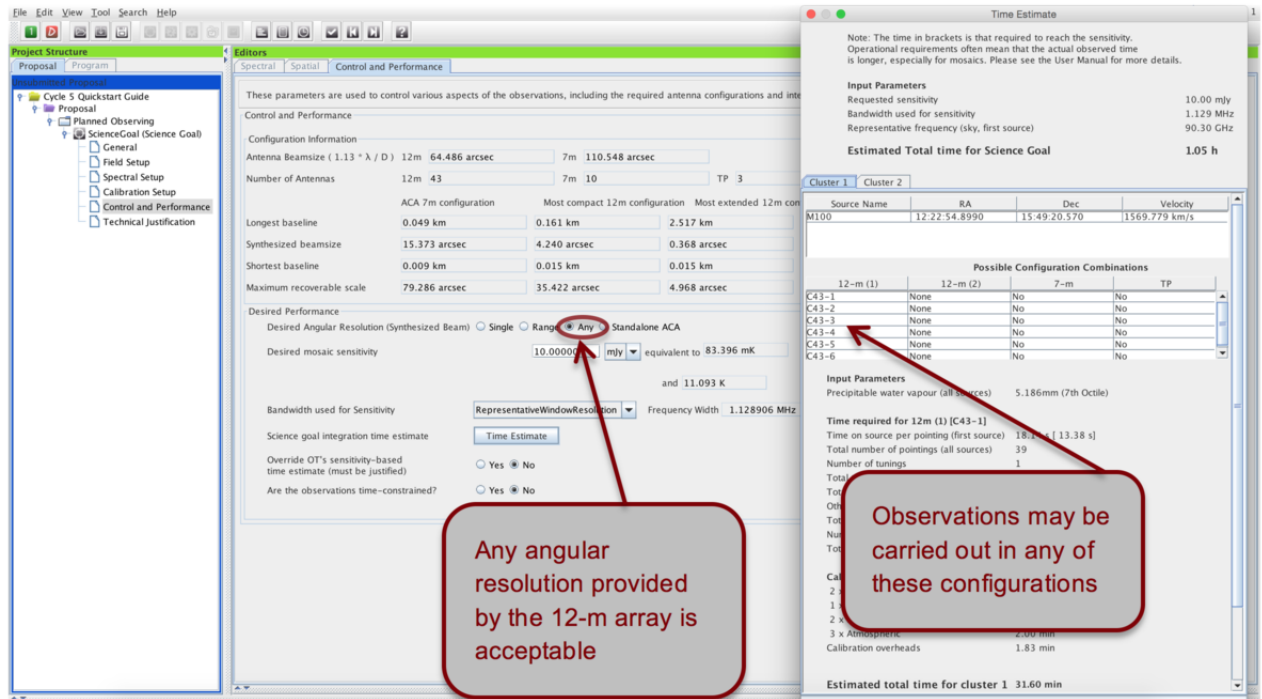

Figure 12: The user has specified that *Any* angular resolution is acceptable.

or more configurations that match the AR anywhere in the specified range. **This gives more flexibility for scheduling observations where the AR requirement is only loosely constrained.** Note that if an AR range is given and the sensitivity requirement is entered as a brightness temperature, the OT assumes the most extended configuration when computing the time estimate as this requires the most time. The equivalent brightness temperature achieved for the more compact end of the AR range is indicated for information only. The *Any* button (see Fig. 12) in practice limits the AR to the values given in the *Configuration Information* for the most compact and most extended 12-m configuration, excluding long-baseline configurations (since these are less efficient to calibrate). For this option users must enter the requested sensitivity in Jy.

It is no longer the case that every configuration will be visited during a cycle. In Cycle 8 2021, for example, the two largest configurations (C-9 and C-10) will not be visited. The OT will be configured to know which configurations are available and will adjust the achievable angular resolutions accordingly.

ACA stand-alone observations are requested explicitly by selecting *Standalone ACA* as the option for the *Desired Angular Resolution*. If necessary to achieve the LAS requested, Total Power observations will be added only for spectral line observations in Bands 3–8. Note that for stand-alone observations the ACA 7-m time estimate is specifically computed for the sensitivity requested, rather than being a multiple of the 12-m Array time. Given the greatly reduced total collecting area of the 10 7-m antennas compared to the 12-m array, a stand-alone ACA proposal will require significantly more ACA time for the same sensitivity request.

You can define and check technical details of the observations using the following fields (fields displayed in red must be filled):

- **Desired Angular Resolution:** your choice is guided by the *synthesized beamsizes* corresponding to the most compact and most extended configurations available in the current cycle as displayed in the *Configuration Information*. The value(s) entered cannot be smaller than the synthesized beam size of the most extended configuration and cannot be larger than the synthesized beam size of the most compact

configuration.

- **Largest Angular Structure in source:** here you should enter the largest angular structure that you **wish to image** in your source(s), which may be different from the actual size of the source. The value entered determines whether you need multiple 12-m configurations and/or the ACA, and therefore has a direct influence on the time estimate (see the *Maximum recoverable scale* for the 12-m configurations in the *Configuration Information* table for guidance). The input units are the same as for the angular resolution. It is not used if an angular resolution of *Any* is selected.
- **Desired Sensitivity per Pointing:** you should enter the sensitivity required for the **most restrictive** line/continuum observation to achieve the scientific aims of the Science Goal, and if relevant mention the S/N achieved for the remaining lines/continuum in the Technical Justification. In the case of a rectangular field mosaic you should specify the sensitivity required over the mosaic, not that for individual overlapping pointings. We recommend that the sensitivity requested is good enough to give a  $3\sigma$  detection at the very least, ideally  $5\sigma$ .
- **Bandwidth used for Sensitivity:** for continuum observations, this field is automatically set to *AggregateBandwidth*. For spectral line or spectral scan observations you can pick one of six choices given in the dropdown menu:
  - *RepresentativeWindowBandWidth*: the bandwidth of the spectral window chosen as the representative spectral window (and containing the *Representative Frequency*) in Section 6
  - *RepresentativeWindowResolution*: the (Hanning-smoothed) spectral resolution of the representative spectral window, taking into account spectral averaging. This is the default for spectral-line setups
  - *AggregateBandwidth*: the summed, non-overlapping bandwidth of all your selected spectral windows. This is the default for single continuum
  - *LargestWindowBandwidth*: the bandwidth of your widest spectral window defined
  - *FinestResolution*: the finest (Hanning-smoothed) resolution of any spectral window, taking into account spectral averaging
  - *User*: a bandwidth of your choice (useful if you are intending to smooth your data after observation to achieve a certain S/N)

Observations requesting very small angular resolutions (i.e. those making use of long baselines) are inefficient because they need to be frequently calibrated to correct for atmospheric phase fluctuations. Since the array configuration is determined based on the AR defined in the OT, it is possible to inadvertently trigger long baseline observations by entering an AR just slightly smaller than that actually required. You can see if the observations defined make use of long baselines in the time estimate pop-up – the first 12-m configuration will be labelled C43-7 to C43-10 and the number of phase calibrator observations per SB execution will be larger than usual. Long baselines should be avoided if they are not necessary to achieve a Science Goal.

Please pay close attention that the *Bandwidth used for sensitivity* is appropriate for your scientific aims. For spectral line observations we recommend that it is at most 1/3 of the expected spectral line width. Selecting too wide a bandwidth will lower the time estimate but yield too low a sensitivity.

The *Time Estimate* button will estimate the total time required to achieve the desired sensitivity goal on the largest array, either the 12- or 7-m, including calibration (pointing, bandpass and phase, as well as flux calibration if requested and reference positions for TP observations) and overheads (telescope slewing, computational latencies). The time for the smaller configurations is estimated using multiples of the time required for the largest array. The multipliers are based on simulations – see the Technical Handbook for more details.

Additional options that affect the time required are:

Figure 13: The time constraints interface and Time Estimate box for the example of *Multiple Visits* and *Simultaneous 12-m and 7-m observations*.

- **Override OT's Sensitivity-Based Time Estimate:** If your Science Goal is not sensitivity driven, but instead requires a certain time (e.g. for a monitoring experiment) you can choose to override the OT's time estimate. The time entered should be the total time (including calibrations and overheads) for the more extended 12-m configuration needed; time estimates for the ACA are the automatically calculated by the OT.
- **Are the Observations Time-Constrained?:** The OT has the ability to capture the following time constraints:
  - *Single Visit:* specify fixed time intervals during which your observations should be executed. The observations will be carried out **only once in total**, within any of the time windows specified. You can manually *Add* time windows individually or *Import* a list of time slots from an ASCII file. See the Control & Performance section of the [ALMA OT Reference Manual](#) for the format required.
  - *Multiple Visits:* define multiple visits for your Science Goal. The timing constraints of the individual visits are specified in terms of arbitrary, fixed or relative time intervals. Here, the observations will be carried out **once for each visit specified**. The time estimate computed by the OT will be multiplied by the number of visits (see Fig. 13).
- **Simultaneous 12-m and ACA observations:** If this is selected, it is assumed that the observations will be observed at the same time. The total time required for the largest array configuration will also be assigned to the smaller arrays.

Figure 14: The technical justification editor.

Selecting *Tool* in the OT menu gives you access to a number of useful tools to help you better plan your observations. You can use the **Sensitivity Calculator** to bring up a pop-up window that allows you to experiment with project execution times and sensitivities, the **Project Time Summary** (“clock” icon) to give a time and data-rate summary, and generate **printable and PDF summaries** of individual Science Goals as well as the whole proposal (including a cover sheet).

## 10 Technical Justification

For the majority of proposals, the technical justification is entered in three sections: Sensitivity, Imaging, and Correlator configuration. Relevant parameters are taken or computed from the Science Goal setup and the Expected Source Properties are displayed for each section. If the OT detects values it thinks should be double-checked, an informative message is displayed in blue. You should pay special attention to these issues in your justification text. Note that any supporting figures (e.g. simulations) should be included in the science case PDF.

You must enter a short justification text in the free-format text boxes of each section. In addition, text boxes will appear for any choices that need to be justified. These include using single polarization, non-standard continuum frequencies, non-Nyquist spatial sampling, a user-defined calibration strategy, overriding of the OT’s suggestion of the ACA or time estimate, low maximum elevation of a source and time-constrained observations. For detailed guidelines on filling the Technical Justification please see the [Proposer’s Guide](#) and the technical justification [video tutorial](#).

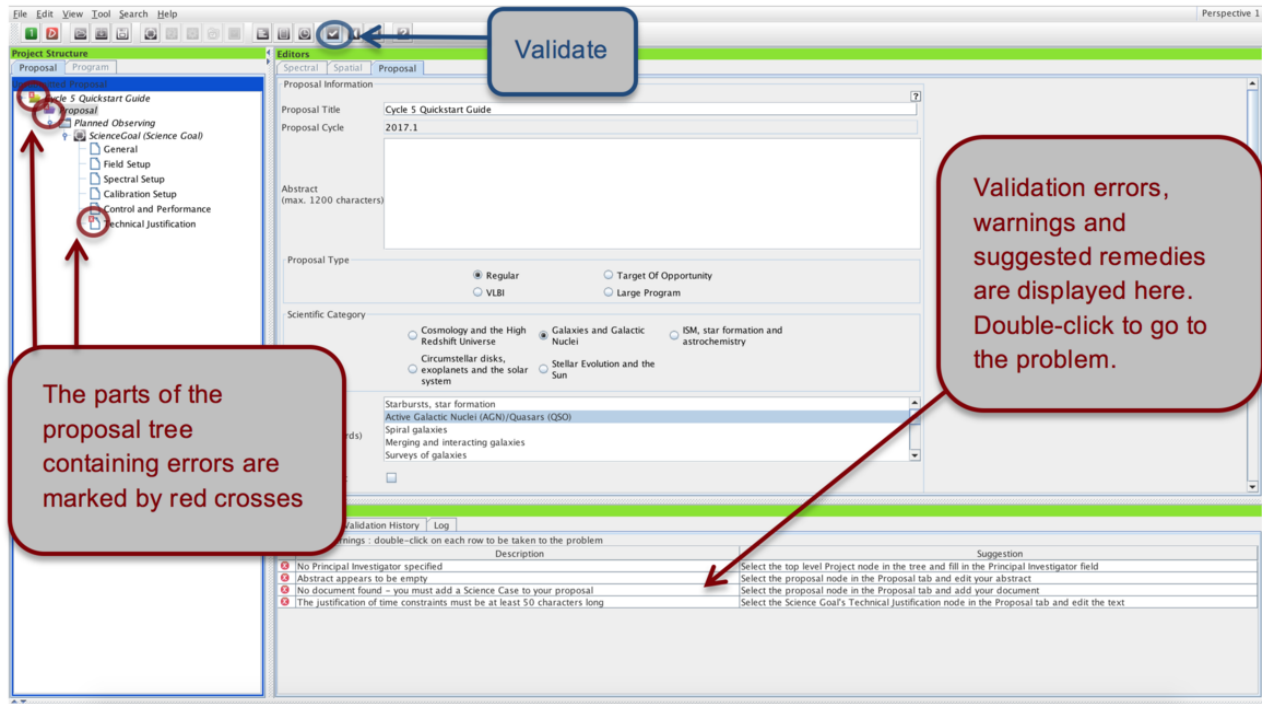

Figure 15: An example of failed validation.

## 11 Validating and Submitting

A proposal must pass validation before it can be submitted. This is most easily checked by clicking on the “tick” icon in the toolbar which will cause any errors or warnings to be shown in the Feedback pane (see Fig. 15). Warnings are for your attention and should be double-checked, but they do not prevent you from submitting a technically sound proposal. Double-clicking on an error/warning message will take you to the relevant Science Goal so that you can easily identify and correct the problem. With all errors corrected, your project is now ready to be submitted.

To submit your project to the ALMA archive select *File > Submit Project* in the menu bar. You and all of your Co-Is should receive a confirmation email after each proposal submission. Once you have submitted, the *Unsubmitted Proposal* label in the blue proposal status bar will be replaced by a red *Submitted* label. This indicates that the proposal has been stored in the ALMA archive and assigned the *Project Code* listed in the titlebar of the OT GUI. You are encouraged to save your project to disk after submission in order to ensure that any updates are made on the submitted version.

You can make changes and re-submit your *Submitted* proposal until the deadline; any re-submission will overwrite the previous version of the proposal stored in the archive. For more detailed information on the ALMA OT and the technical capabilities in the current cycle you are invited to consult the documentation available on the Science Portal. If you have any questions or comments please feel free to submit a ticket to the ALMA Helpdesk.

The Atacama Large Millimeter/submillimeter Array (ALMA), an international astronomy facility, is a partnership of the European Organisation for Astronomical Research in the Southern Hemisphere (ESO), the U.S. National Science Foundation (NSF) and the National Institutes of Natural Sciences (NINS) of Japan in cooperation with the Republic of Chile. ALMA is funded by ESO on behalf of its Member States, by NSF in cooperation with the National Research Council of Canada (NRC) and the Ministry of Science and Technology (MOST) in Taiwan and by NINS in cooperation with the Academia Sinica (AS) in Taiwan and the Korea Astronomy and Space Science Institute (KASI).

ALMA construction and operations are led by ESO on behalf of its Member States; by the National Radio Astronomy Observatory (NRAO), managed by Associated Universities, Inc. (AUI), on behalf of North America; and by the National Astronomical Observatory of Japan (NAOJ) on behalf of East Asia. The Joint ALMA Observatory (JAO) provides the unified leadership and management of the construction, commissioning and operation of ALMA.
